Fibromyalgia and Aging: The Role of Time-of-Day in Cognitive and Physical Performance

Introduction

Fibromyalgia

- Fibromyalgia (FM) is a chronic condition characterized by widespread pain, fatigue, stiffness, and concentration problems (Wolfe et al., 1995).
- FM affects between 2-6% of Americans; approximately 90% of those affected are women (Lawrence et al., 2008; Wolfe et al., 1995).
- The prevalence of FM increases with age, reaching greater than 7% in women 60-79 years of age (Wolfe et al., 1995).
- FM has a high rate of co-morbidity with anxiety and depression (Aguglia et al., 2011).
- Common FM symptoms of depression and fatigue are related to higher levels of impaired cognition (Suhr, 2003) and physical functioning (Jones et al., 2010).
- But are cognitive and physical performance affected by time of day in FM?

Time of Day

- Generally, circadian patterns for older adults tend to favor morning as a time for peak performance (Roenneberg et al., 2003; Martin et al., 2008).
- Symptoms of FM, however, may disrupt typical circadian and performance patterns.
- 80% of those diagnosed with fibromyalgia suffer from broken sleep (Scheuermann, 2009).
- Poorer sleep appears to result in more pain the following day (Affleck et al., 1996)
- With FM, pain, stiffness, and fatigue tend to be greater in the morning, especially for those with low pain tolerance (Bellamy et al., 2004; Riva et al., 2010).
- Fatigue is often worse early in the morning and again later in the afternoon (McIlwain & Bruce, 2003).
- Pain tends to increase again later in the day (McLean et al., 2005)

Purpose of Study

The current study compares the physical and cognitive functioning of older adults with FM to their same-aged healthy peers to determine whether time of day might moderate the relationship between FM status and performance.

Hypotheses

An interaction between FM status and session is expected, with FM participants performing better on the cognitive and physical tests later in the day and non-FM participants doing better in the morning.

Method

Participants

Procedures

- second day

Measures

- Time of Day

 - 9:00 a.m.
 - 11:00 a.m.
 - 1:00 p.m.
- Covariates
- Age
- Gender
- Cognitive Measures

- Physical Measures

William A. Moreno, III, Adam Bateham, and Laura Zettel-Watson

 Community dwelling, functionally independent adults over 50 70 individuals with FM • 5 males, 65 females 76 healthy controls • 25 males, 51 females

Mailed information and consent documents, health history, activities/demographic survey, other questionnaires

2 days of testing (~2 hours/day); physical and cognitive testing took place on

 Cognitive tests took 35 - 60 minutes Physical tests took about 25 minutes

3 testing sessions, beginning at:

 Stroop Color (Stroop C) and Color/Word (Stroop CW) Tests (Trenerry et al., 1989); scores = seconds to complete

Trails A & B (Lezak, 1995); scores = seconds to complete

 CERAD 10-item word list assessing immediate (3 trials) and (10-15 minute) delayed recall, plus a 20-item delayed recognition trial (Morris et al., 1989); score = total number correct across all trials

 Digit Span Forward and Backward (Wechsler, 1997); scores = # correct Digit Symbol Substitution (Wechsler, 1997); scores = number correct in 120s Animal fluency; scores = number named in 60 seconds

 Fullerton Advance Balance scale (FAB; Rose, Lucchese & Wiersma, 2006); score = 10-item total

Senior Fitness Test (Rikli & Jones, 2001):

• 30-second chair stand (# of stands)

• 8 Foot Up and Go (# seconds)

• 6 Minute Walk (distance covered in 6 minutes)

Preferred Walk Velocity (30ft./#sec at preferred gait)

Maximum Walk Velocity (30ft./#sec at maximum walking speed)

Table 1: Descriptive Characteristics of FM and Non-FM Participants

Age

Gender Male Female

Performance Measures CERAD Total Animals Digit Span Forward Sco Digit Span Backward S Trails A Time (# seconds Trails B Time (# seconds Stroop C Time (# second Stroop CW Time (# seco Digit Symbol Substitut FAB 30-sec Chair Stand (# o 8 Foot Up and Go (# sec

Preferred Walk (# secon Maximum Walk (# seco

Results

Cognitive Findings

- Session did not moderate the relationship between FM status and memory (CERAD), processing speed (DSST, animal fluency) or executive functioning (as measured by Trails A & B, Digit Span).
- Only executive functioning (as measured by the StroopCW) revealed an interaction, but not in the expected direction (see Figure 1).
- FM participants performed better than the non-FM participants in the morning but performed worse in the afternoon (p < .05).

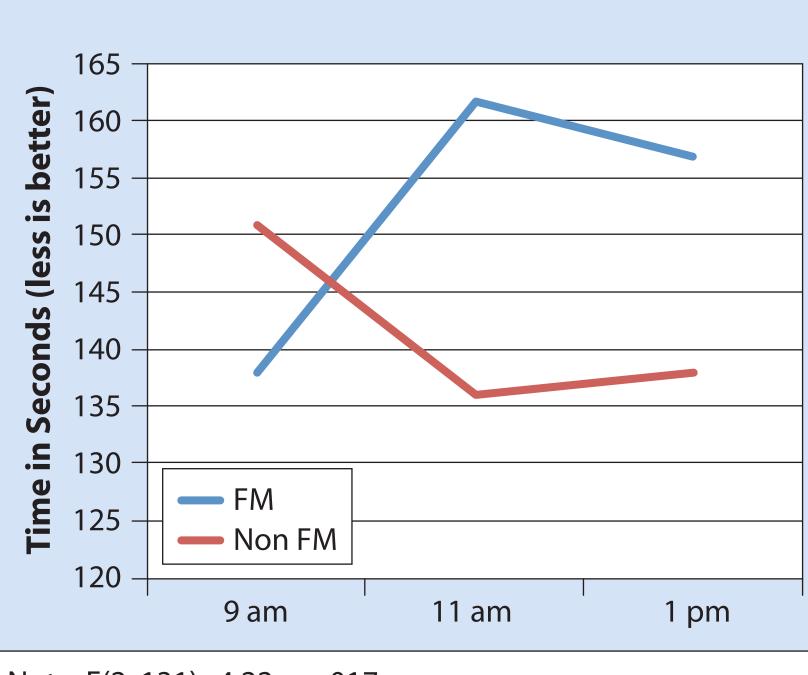

Physical Findings

- Session did not moderate the relationship between FM status and balance (FAB) or lower body strength (30s chair stand).
- A significant FM status X session interaction was found when predicting performance on aerobic endurance (6-minute walk) and overall functional mobility (8 foot up and go) (see Figures 2 & 3).
- Marginally significant interactions were found for preferred and fast walk velocity (ps < .08).</p>

Separate 2 (FM status) X 3 (time of day) MANCOVA analyses were performed on the data for the respective cognitive or physical measures. Age and gender were included as covariates.

Figure 1. Interaction of FM Status and Time of **Day on Stroop CW Performance**

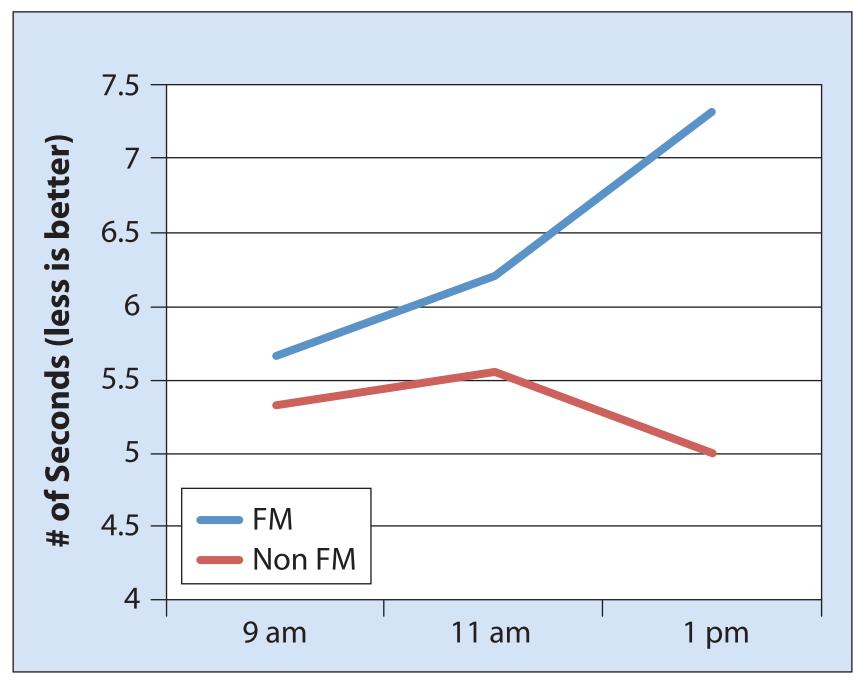

Note: F(2, 131)=4.22, *p*=.017

Figure 2. Interaction of FM Status and Time of Day on 6 Minute Walk Performance

Note: F(2, 128)=5.76, *p* = .004

Figure 3. Interaction of FM Status and Time of **Day on 8 Foot Up and Go Performance**

Note: F(2, 128)=3.20, p=.044

Conclusions

- Participants with FM tended to perform better earlier in the day (not later, as was expected).
- Non-FM participants were generally unaffected by time of day.

Implications

- Discovering one's "peak" time of day can be beneficial for those with and without FM
- Medications and other treatments could be administered on a schedule that reflects a person's performance fluctuations.
- Activities could be scheduled during a person's peak hours.
- Clinical assessments and research studies should consider participant test times to insure accurate results.

Limitations and Future Directions

- No random assignment to sessions, so self-selection was possible in the current study; random assignment should be included in future studies
- Future studies should continue investigating the physiological mechanisms related to circadian differences in those with and without FM. For example:
- HPA axis/cortisol link (Riva et al., 2010)
- Sleep patterns/phase advancing (Epstein & Mardon, 2007)
